INTRODUCTION

St

INTRODUCTION

Once upon a time it was not easy to write and play games with computers. Back in the dim, dark past, it could cost you \$80 to \$100 an hour just to rent access to a time-shared mainframe via a terminal. And the only output you had was on the printout of a noisy, hard to read teletypewriter. Think what those restrictions would have done to your current pattern of spending hours lovingly debugging, and improving, your latest masterpiece.

We, fortunately, do not have to suffer such medieval conditions. The luxury of having a computer of your own, driving a TV screen, with unrestricted access to the machine, allows you to work for as long as you like creating games and other programs.

In this book, you'll find a collection of our favorite computer games. We hope some of them will soon be up and running on your computer, and are stored with your own favorite programs. They're sure to provide you with a lot of fun in the weeks ahead.

(By the way, from now on, we'll use "I" in this book, rather than "we" which sounds too much like the "royal we". "I" seems to read better.)

I've deliberately written the book so that it is 'open-ended'. That is, in contrast to many other collections of games programs on the market, I've assumed you'll want to adapt and improve the programs once you get them up and running. Therefore, with many of them I've included program breakdowns, some line by line, so you know what each section of code is doing. As well, the introduction to each section discusses a bit about the philosophy of writing games of that type, has a word or two to say about the basic algorithms which you can use to create games of that sort yourself, and generally aims to give you a solid background against which

you can expand and develop your own games-writing skills.

Near the back of the book you'll even find a section devoted entirely to game ideas which you can convert into computer games.

To maximise the length of program you can get into your machine (and to keep program entry time down to a minimum) few of the programs include instructions. These are in the text. However, if you have the memory (and the inclination) you can easily add a "Do you want instructions" line as part of the initialisation subroutine, and then include a shortened form of the instructions from the text in your program.

I think we should get to the fun parts immediately.

Good game-playing,

Tim Hartnell

Glen Pringle

Board Games

Board Games

Some games could not have existed without computers.

Think of the whole range of Space Intruder types of games and the Pacperson ones. These could have not come into being before the computer - using a TV-like screen for output - was developed. Many other games, of course, predate the computer by thousands of years. However, more and more of these traditional games have now been computerised, with board games being as popular with computer game players as they were with players in precomputer days.

In this section of the book, we have a generous crop of board games:

- * GOMOKU
- * FOUR IN A ROW
- * CHECKERS
- * KNIGHTSBRIDGE

We'll start this section of the book with a discussion on how board games can be easily modified to make it possible for a computer to handle them. There is a common thread which holds together all the programs in this section of the book, a thread which you can also use to help you develop programs to play your favorite board games.

Look first at this diagram. It shows a checkerboard numbered to make it easy for the computer to handle.

	1	2	3	4	5	6	7	8
8	81	82	83	84	85	86	87	88
7	71	72	73	74	75	76	77	78
6	61	62	63	64	65	66	67	68
5	51	52	53	54	55	56	57	58
4	41	42	43	44	45	46	47	48
3	31	32	33	34	35	36	37	
2	21	22	23	24	25	26	27	28
1	11	12	13	14	15	16	17	18

You can indicate any square on the board by referring to the number along the left hand side,

(such as 3), then the number along the top (such as 4). In this case, the lines numbered 3 (along the left hand side) and the line numbered 4 (along the top) meet at the square numbered 34. If you wish to move a piece, you can do so by entering the number of the square you're moving from (such as 55), then the number you're moving to (such as 66) and the computer can understand exactly what you're doing. There is no need to change the numbers entered by the human player into another set in order to allow the computer to interpret them.

That is the first 'secret' of writing board games so your computer can play them. The second is that a board numbered in this way has another great advantage over one which is simply numbered from one to 64 in order. When you move a piece in any direction on this board -- no matter where you start -- the difference between the squares is the same.

I'll try to expand on that somewhat cryptic statement. If you move one square up and to the right -- like the move of a piece in checkers -- you will move from, say, 24 to 35; or from 53 to 64; or from 71 to 82. But notice that no matter where you are on the board, the difference between your starting and ending squares is always 11. If you move diagonally up to the left, you'll move from, say, 26 to 35 (plus 9), or 66 to 75 (also plus 9) or from 22 to 31 (plus 9 again).

This predictability makes it relatively simple to create a board which the computer can handle.

How the computer plays

Imagine the computer has a checkers piece on the square numbered 24. It could be programmed to check each square on the board, and every time it found one of its own pieces, could check if there was a human piece on the square numbered the same as its

piece (that is, 24 in this example), plus 11 (that is, on 35); and it could check to see whether the square which was 11 past that, 46, was blank. If it found that all these conditions were true, the computer could jump over square 35 into square 46, and capture the piece currently occupying 35.

This, in essence, is how many computer board games -- from checkers, through reversal, to chess -- work, based on a simple 8 by 8 grid numbered in this way.

If you were writing chess you could specify the moves of the knight by knowing it can always move to squares which are the following 'numerical distance' from the square on which the piece now sits:

21 12 -8 -19 -21 -12 19 8

Try it now, by placing a coin on square number 55, and move it as if it were a knight, working out the mathematical relationship between the starting square, and the square you're moving to. You should find the differences are the same as the numbers listed above.

The programs in this section, and in many other parts of this book, were written in a 'top down' manner, in an attempt to produce a structured program which is relatively easy to follow and modify. Many of the programs were written by entering the following 'bare code' at the start:

```
10 REM NAME OF GAME
20 GOSUB 8000:REM INITIALISE
30 GOSUB 8000:REM PRINT BOARD
40 GOSUB 1000:REM COMPUTER MOVES
50 GOSUB 8000:REM PRINT BOARD
60 GOSUB 7000:REM HUMAN MOVES
70 Check if human has won or computer has
   won and if so branch to end of
```

game message...
80 GOTO 30

This structure was written, in nearly all cases, before I had the slightest idea how I was to accomplish the goals I had set myself for each of the subroutines.

All programs were written out completely on paper before the computer was even turned on, so that a version of the game could be 'hand run' before starting to actually grapple with the game on the computer. This enable the worst bugs to be caught right at the beginning.

Among the many great advantages I discovered regarding programming on paper in this way was the willingness with which I completely discarded whole blocks of code if they were found to be unworkable. It is much more difficult to decide to erase a whole section of code from a program once you actually have it in the computer than it is to just tear up a piece of paper. The temptation -- when lines of program are actually in the computer -- is to fiddle with them, in an attempt to make them work, at least after a fashion.

Working on paper, then, tends to avoid having code which really should not be in a program somehow being patched together to make it work. Working with a structured outline, such as that I've described, makes it simple to know which parts of the program carry out which task. I know, for example, in the outline above that the board is printed by the subroutine starting at line 8000. Therefore, if the board comes out looking a bit odd, I know immediately which section of the code I should concentrate on.

As well as helping in the early 'get it working' stage, a structured program tends to invite improvements. Once you have, for example, your own Checkers

program up and running, you can go back to it some time in the future to try and make it play a little better by going just to that part of the code which covers the computer's game. You will not have to wade through vast acres of code, trying to work out just what each line does, and which particular lines control the computer's play.

The methods I've just outlined are used throughout this, and most other sections, of the book. It may prove instructive to look through some of the programs to follow through the listing, and work out which section does what. In many programs, you'll see that I've included lines of asterisks as a REM statement. These break the program into separate modules which should help you follow the program through.

GOMOKU

You'll find GOMOKU an easy game to learn, but one which is almost impossible to win. The computer plays extremely well in this program, which is based on one written by Graham Charlton.

You have to try to get five of your pieces (the H's) in a row in any direction, while the computer is trying to do the same.

Have a look at these board positions from the start of one game I played against the program. Studying the printouts will show you how the game unfolds, and will show you how to play it:

FOUR IN A ROW

In this game, FOUR IN A ROW, as its name suggests, the aim is to get four of your pieces (the H's) in a line in any direction, before the computer (using the C's) manages to do so.

You indicate your choice of move by specifying the column in which you want to move your piece. The piece then drops to the lowest available position within that column.

The computer plays this game fairly well, and surprisingly quickly, considering the number of times it can go through those loops within the program.

I was not particularly pleased when I finished the first hand-written version of this program, because it seemed to me that I had taken a 'brute force' approach to solving the problem. I was sure there would be a more clever way to do it. However, I continued with the program, and then entered it into the computer. It won the first game, even though it played a little oddly, so I knew I was onto a winner, despite the programming approach. Then, when thinking about it later I realised that if the program was correctly structured (as it was), had no redundant code (and it hasn't, as far as I can see), ran quickly and well, it did not need 'fiddling' to make the programming more tricky. Transparent code is always better than overly clever convoluted code which, although it may occupy less space, and may run a few microseconds faster, is almost impossible to modify.

So the program you have here is my 'brute force' version. It is generously supplied with REM statements so you have little trouble in working out what each section of code does. It should also prove fairly simple to modify, once you have played a few games with it in its present form.

In this version of FOUR IN A ROW, the computer always allows the human to have the first move, and bases its initial move on that made by the human. You may wish to modify the program so that there is an option for the computer to have the opening move.

Before we get to the Listing of FOUR IN A ROW, here's one game played against the program:

CHECKERS

The game of CHECKERS has a long and honorable history. R. C. Bell (in his book *Discovering Old Board Games*, Shire Publications, Aylesbury, UK, 1980) says it was invented around 1100, "probably in the south of France, using Backgammon tablemen on a chequered chessboard with the Alquerque method of capture" (pp. 35 - 36). The *Encyclopedia of Sports, Games and Pastimes* (Fleetway House, London, c.1935) puts it much further back in time: "Forms of it were known in ancient Egypt, Greece and Rome, while the game was played in the mid-seventeenth century much as it is today." (p. 237).

Regardless of its age, it is a very popular game around the world, with many European countries having regional variations on the game of their own. Continental draughts (checkers is generally known as draughts outside the US), for example, is played on a board of 100 squares with each player starting the game with 20 pieces. It was developed in the early 1700's.

This CHECKERS program plays the game you are probably most familiar with. It plays swiftly, and reasonably well, although its lack of endgame strategy often leads to a dramatic collapse in the final moment of a game.

CHECKERS is played between you and the computer. Each of you is attempting to take (that is jump over to capture, then remove from the board) the other player's pieces, or to confine the opponent's pieces so no more moves are possible.

The game is generally played on a board with 64 squares, which are alternately light and dark. In

this program, the board (as you can see from the sample game we have shortly) is a series of dots, with your pieces shown as H's (for human) and the machine's pieces as C's (for clever).

When the game begins, you're at the bottom of the screen, playing up, and the computer is at the top playing down. As the program is currently set up, the computer always has the first move. If you want the first move then delete line 50.

All moves must be made along diagonals. Individual pieces can only move forward, that is towards the opponent's starting side. Pieces are converted into 'kings' when they reach the back rank across the board. Your kings are shown as K's, the computer's kings are dollar signs. Kings can move either forward or back. After capturing a piece, by jumping over it into the vacant square immediately behind the captured piece, you can move again if there is a further capture which can be made.

KNIGHTSBRIDGE

It is played on a seven by seven board. The computer tells you which piece you must move (each piece is indicated by entering a two-digit number, the first being the co-ordinates of the square you're moving to down the side of the board, the second digit being the co-ordinates of the square across the top), and then leaves you to decide where you will move to. All pieces move like Chess knights, and all moves are checked to see if they are legal before you are allowed to move.

You capture by landing on top of an enemy piece. The first player to capture five of the enemy's seven pieces is the winner. There are no multiple jumps.

You'll find the computer plays swiftly and well.

Adventure

Adventure

Down into the depths of darkness you go. Armed with only your computer, and your keen mind, you have decided to take on the forces of evil.

You may be on a desert island, inside a haunted house, within a dungeon deep within the bowels of the earth, or trapped in a cave system on a planet 'somewhere in a galaxy far away'.

ADVENTURE games take place in all these scenarios, and a thousand more beside. Come with us now, as we discover the excitement of the worlds of ADVENTURE.

The word ADVENTURE is used to describe the class of computer games in which the player moves through an alternative reality. In this 'otherworld' there are monsters to be fought, treasures to be discovered, maps to be made, and puzzles to be solved.

Many people feel that ADVENTURE games are the most exciting games which can be played with a computer. If you are interested in role-playing games like TSR Hobbies' Dungeons and Dragons (the game and name are registered trademarks of TSR), then you're certain to enjoy playing ADVENTURE.

I've included two ADVENTURE-like programs in this book. Both are reasonably difficult to solve, but are most enjoyable. Neither of them are so hard to work out you'll give up in frustration.

One feature of true ADVENTURE games is that the reality they model is consistent. That is, the world created within the ADVENTURE program is solid, and -- apart from any events specific to that game, such as an earthquake, or a magic spell -- the parts of

the world do not shift in a random fashion. If you walk past a 'gnarled and twisted oak, with the initials of your best friend carved in the trunk' when going down a certain woodland park, the same oak should still be there when you return. In a properly constructed ADVENTURE the rivers stay in place, the dungeon walls do not mysteriously move and shift every time you turn your back, and objects you put down in one cave within an underground labyrinth do not suddenly appear of their own volition a hundred caves away (unless, of course, they've been blessed with some form of magical auto-transportation).

Map-making is one of the true ADVENTURE-players skills and delight. Working your way through an imaginary (but self-consistent) environment, tackling monsters and collecting treasures, solving puzzles as you go up and down staircases and chutes, explore side tunnels, get lost in self-circling mazes, and so on is only fascinating if the world you are exploring is mappable. You should, for example, be able to expect both ends of a tunnel to always emerge in the same spots, so when you come across one entrance to that tunnel later on in a game from a different position, you will have a new, useful clue to further flesh out your map of the environment. All the 'worlds' created in the games in this section of your book are mappable.

Role-playing is part of life. There are sure to be many situations in your everyday activities when you, to some extent, are forced to adopt a role. Most jobs, unfortunately, expect you to behave as if the needs and goals of the company were your own needs and goals, that the enthusiasm you project each day to customers and fellow-workers were your own, inner enthusiasms, and so on. You may well find that, in new situations, you have learnt to mask your lack of ease by acting confident, and at ease, discovering that -- if you do it skillfully -- people take the projected role as if it were your true self.

The role-playing which takes place within the imaginary environments of an ADVENTURE game is far more interesting, and is generally far removed from the self of your everyday life. When you think about it, even playing games like 'Cops and Robbers' is an exercise in role-playing.

So, we've all had experience in role-playing, even if some of it was not as much fun as taking part in long-range campaigns to rescue a handsome prince, trapped within a tower. The ADVENTURES given in this book are by no means as elaborate as some of the ones offered for sale for your computer, but they are more carefully and consistently organised than many I have seen, and -- as a bonus -- give you frameworks within which you can construct ADVENTURE programs of your own.

Role-playing games which involve other people, such as TSR's D & D which I mentioned earlier, generally have a great deal of flexibility in development as a game proceeds. Under the control of a good Dungeon-master, a role-playing game can develop and evolve in directions which he or she had not even imagined when setting up the initial scenario. Unfortunately, computer role-playing games cannot be so flexible. In many ways when playing ADVENTURE with a computer, you are trying to solve a puzzle, or series of them, which the programmer has created. The computer can be used to help set up the initial scenario and determine where objects will be located, and perhaps where a particular stairwell will lead, but the overall shape to the environment is fixed by the programmer when the game is written.

You can see this in action, for example, in our program STRONGHOLD OF THE DWARVEN LORDS where you have to work your way through a maze to discover where the Dwarven treasure is stowed. The computer actually hides the treasure, and modifies the '3-D maze' to some extent, but that is all. Of course, the computer is also used to produce the feedback to the player as the game is underway, and its role there is very valuable.

Once upon a time, war campaigns were re-enacted on table tops. Napoleonic battles were fought and won on large sheets of card marked with rivers and woods, as players re-enacted major engagements within wars, or created their own. Wargamers found the pleasure of the games they played could be increased if attention were paid as much (if not more) to the individuals they were fighting with, rather than just with squads of soldiers. This attention to individual identity lead directly into the role-playing games we have today, as gamers discovered how rewarding it was to take on the role of a particular leader.

Our Dungeons and Dragons developed directly from the war games where players took on the identities of individuals within battles. Two gamers, Dave Arneson and E. Gary Gygax decided to codify an entirely separate reality, which they initially gave to the world in 1974 as a boxed set of three booklets under the title Dungeons and Dragons. The game became an enormous success, and now hundreds of thousands of people spend a significant portion of their leisure plunging into the depths of the earth, as clerics, trolls, magicians and sorcerers, exploring, fighting, conquering -- and occasionally dying -- as they go.

The original D & D idea soon spawned a host of other games, such as Runequest (Chaosium Ltd, Albany, California), Bushido and Chivalry & Sorcery (Fantasy Games Unlimited, Roslyn, New York), Tunnels & Trolls (Flying Buffalo, Inc., Scottsdale, Arizona), Traveler (Game Designers' Workshop, Bloomington, Illinois) and Heroes of Olympus (Task Force Games, Amarillo, Texas).

Will Crowther and Don Woods entered computer history in 1976 by putting the world's first role-playing game -- just called ADVENTURE -- onto a mainframe computer at Stanford University. (The program was actually written by Crowther, and elaborated by

Woods, although today both men are generally credited with development of the program.) Although the game quickly became a cult-pursuit all over America, the floodgates to computer ADVENTURE-gaming did not open until microcomputers put machine-power -- and computer time -- into the hands of millions. Cheaper memory enabled extremely elaborate adventures to be created, and so now the computer ADVENTURE gamer is extremely well served.

Crowther and Woods perhaps created better than they knew. Even today, despite the multitude of programs available, the original ADVENTURE is still going strong. At least five companies at present are selling versions of the original ADVENTURE for the Apple alone.

This original program was written in Fortran, and when it was added to a free software-exchange library (Decus) organised by the Digital Equipment Computer Users' Society (most of whom used Dec's DCP-11 system), it soon became the most-used program in the library. Two years later, another adventure program, Dungeon, was added to Decus. This program which took the ADVENTURE idea much further than Crowther's program, was written by Tim Anderson, Marc Blank, Bruce Daniels and Dave Labling, all of the Programming Technology Division of the MIT Laboratory for Computer Science.

The Addison-Wesley Book of Apple Computer Software (edited by Jeffrey Stanton and John Dickey, The Book Co., Lawndale, California, 1981) devotes 28 pages to describing fantasy, role-playing, adventure and war simulation games available for the Apple II. If the support for that computer is so good in this field of software, it indicates that many other popular computers are also well-supported.

Although there is a trend towards graphic-based adventures, rather than the classic text-based ones, the attraction of text programs continues. Just as

television did not make radio obsolete -- because the imagination is stronger than anything man can make -- so graphic adventures have not taken away the special value of text-based games, where the mind is triggered to produce worlds far more fantastic than any that a clever programmer could draw using the sophisticated graphics available on many of today's machines.

One of the leading companies in the world producing ADVENTURE programs is Adventure International, founded by Scott Adams. His company has some of the most imaginative displays at computer shows of anyone in the games software field, and it is good to know his programs are as exciting as his show displays. Make sure you experience the pleasure of playing a Scott Adams adventure program in due course, and you'll see how far the genre has been extended.

I met Scott in Atlanta one day at a computer show and found him friendly, quiet and reserved. Somehow, I'd expected him to be like a warlock from one of his dungeons, or a dragon from one of the cave systems. However, some behaviour was more in keeping with my expectations. It was Halloween, and Scott and his crew were all dressed to the nines as characters out of some of the programs. The same approach to life which had him tell his staff to come to work in fancy dress permeates his programs. Start with the programs here, which are much simpler to solve than programs such as Scott's, and then graduate to the commercial programs. Perhaps his program Adventureland would be a good place to begin, before you move on to some of his other games, and onto those produced by other companies.

I guess it's time now to introduce you to the adventure programs in this book. If you'd like to know more about the field, to help you write your

own programs, there is a vast body of literature which is of interest. It includes:

- PUTTING ADVENTURE IN ADVENTURE GAMES - article in Creative Computing, August 1981, by Robert Plamondon
- GRAPHIC ADVENTURES ON THE ATARI - article in Creative Computing, August 1982, by John Anderson
- FANTASY GAMES (parts one and two) - articles in Creative Computing, issues of March 1981 (part one) and May 1981 (part two) by David Lubar
- AN ADVENTURE IN SMALL COMPUTER GAME SIMULATION - article by Scott Adams (when he was just about unknown!) in Creative Computing, way back in August 1979
- KINGS OF THE CASTLE WALLS - article in Practical Computing, March 1982, by Dennis Ellis
- ADVENTURE WRITING - this is an immensely valuable 16-page booklet, distributed by Aardvark-80, 2352 S. Commerce, Walled Lake, MI 48088 (313 669 3110) for around \$5.00. It explains the whole background of adventure game writing, and includes a complete adventure program, Deathship. If you read nothing else in the field, you should get hold of this booklet if you really want to discover how to write adventure games
- FANTASY ROLE-PLAYING GAMES - Holmes, J. Eric (Hippocrane Books, Inc., New York, 1981)
- WHAT IS DUNGEONS AND DRAGONS? - Butterfield John, Parker Philip, and Rohigmann David (Penguin Books, New York, 1982)
- DICING WITH DRAGONS - AN INTRODUCTION TO ROLE-PLAYING GAMES - Livingstone, Ian (Routledge & Kegan Paul, London Melbourne and Hanley)

STRONGHOLD OF THE DWARVEN LORDS

Deep beneath the earth you go, far into the Dwarven Heartland. Danger is on every side as you descend, but your greed draws you on. Searching through the dusty stacks of uncatalogued manuscripts in room 546B of the British Museum, you came across a faded, and almost illegible map to a Dwarven hoard of gold, and since that day, you have been obsessed with the idea of finding it.

As you go down into the labyrinth, you realise that the Dwarven Lords, who secreted the gold here 7389 years ago, have long since become extinct, so the main danger you face is from the layout of the cavern system itself, rather than from Guards of the Stronghold.

In STRONGHOLD OF THE DWARVEN LORDS you are in a cavern which holds the gold. Each time you play this game, the gold can be in one of three places. The only information you get as to your progress is information provided by the Dwarven Source Beam which you found as you made your way into the cave system. This gives you feedback after each move as to the location of the gold, but you need to learn how to interpret the information it gives you before you'll be able to make much use of it.

The other information you get is in the form of a

straight statement regarding the directions you can move from your present position. After each move ['step'], you'll be given a screen display like the following:

STEP NUMBER 49

NORTH: WALL
SOUTH: OPEN
EAST: WALL
WEST: OPEN

THE DWARVEN SOURCE BEAM READS 10

Then you'll be asked to enter the direction you want to move, as follows:

WHICH DIRECTION DO YOU WANT
TO MOVE?

N - NORTH, S - SOUTH
E - EAST, W - WEST, H - HELP

You will not, as you probably realise, be allowed to walk through walls.

The aim of the game, needless to say, is to reach the Dwarven riches as quickly as possible. To aid you, there is a map of the cavern system from above, which you can call up from time to time.

There are two catches to calling up a map of this type. Firstly, although you are shown, the location of the gold is not. Secondly, each time you enter 'H' to get a look at the map, you'll be penalised 15

steps. Therefore, it is in your interests to use the Help option as few times as possible.

Although there are some features which are common to each and every cavern generated by this program (dictated by the data statements from 860 to 950), the cavern is not identical from run to run. As well as that, as I mentioned earlier, the gold itself can be in one of three locations within the cave system.

The output of the program, as it is given in terms of the directions you can take from your present position, could be modified to produce a '3-D maze' output. You know, from move to move, which direction you're facing, and the computer knows which directions from that position represent possible moves. You would need to add a subroutine which drew a picture of the situation immediately in front of you, choosing from a bank of pictures (one with the area straight in front of you clear but with the walls solid on either side of you, another with entrances to the right and to the left but with the path straight ahead blocked off, and so on) to

produce a continuous picture of the scene ahead. This can be most effective, and may well be worth implementing on your system.

Now, here is the listing of STRONGHOLD OF THE DWARVEN LORDS so you can start trekking for gold:

THE DUKE OF DRAGONFEAR

THE DUKE OF DRAGONFEAR puts you into another grid system world, but one which is populated with a range of fearsome possibilities including pits containing quicksand or dragons, as well as magic caves which can transport you at random within the land of Dragonworld, and caves filled with Dragon's gold.

When you first run the program, you'll get this quick peek at a map of Dragonworld:

[illegible]

In this map, X represents a wall you cannot pass or a cave you cannot enter, H (for human) is you starting in about the centre of the system, \$ is the treasure caves, ? the magic transportation caves, D represents dragons and Q tells you that cave contains quicksand. Obviously this is a world filled with potential pleasures as well as dangers.

If you're a veteran of computer games, you may well recognise that THE DUKE OF DRAGONFEAR is a development of the Hunt the Wumpus games. Wumpus is one of the grand old standards of computer games, in which

you are in a cave system, looking for one or more mythical beasts known, in the singular (and these are most singular beasts) as Wumpus. Wumpii we are assured, by those who care about such things, is the plural. Anyway, in essence, a grid is set up in such games, and objects, people, effects, monsters and whatever else you choose are placed at locations on the grid. From time to time, if you so decide, one or more of the contents of specific cells of the grid may move. The human player, of course, can also move from cell to cell within the grid.

Generally, there is no overall visible map of the system, although some programs (such as THE DUKE OF DRAGONFEAR) do provide such information for players. The very first Wumpus game was written by Gregory Yob in 1975. In David Ahl's superb book More BASIC Computer Games (Creative Computing Press, Morristown, New Jersey, 1979), Mr Yob explains how he was visiting People's Computer Company, in Menlo Park, California, to see the programs they were developing, and he noticed there were three 'hunt the something' programs being written, each on a 10 X 10 grid, and each of which gave feedback to the player in terms of 'no, no...try to the northwest'.

Disenchanted, Mr Yob returned to a lonely time-sharing terminal (back in those ancient days, gentle reader, human beings did not have little computers at their back and call) and hammered out the program which eventually became the very first 'Hunt the Wumpus'. Mr Yob had the creature dwelling in a dodecahedron-shaped cave system.

Mr Yob's inventive genius did not stop at this point. He peopled the cave with 'magic bats' which moved you from place within the system at random, with bottomless pits, and ensured that the arrows with which you were equipped when you entered the system could fly round corners.

You can see now how this framework became the heart

of the Wumpus programs which have proliferated around the world and which formed the very basic framework upon which THE DUKE OF DRAGONFEAR is based. This program gives you more control on the outcome of the program, adds treasure to the caves, and imposes a time-limit to your game.

As well, you are equipped with a 'magic amulet' which can see into the caves which are around you. Unfortunately, because you're not much of a whizz when it comes to evoking magic, the old amulet doesn't work too well. It can only tell you of the contents of one of the eight caves surrounding the one in which you stand, and worse than this does not tell you which of the eight it is referring to. It

```

X X X X X X X X X
X . D D $ ? D . . X
X D X . . X . . X
X D . . . Q . X X
X Q . . . . . X
X . . . . . $ ? X
X $ $ . . . X . ? X
X . X . . . . . X
X . Q Q H . . . X
X X X X X X X X X

```

is not as bad as it may sound. You'll be surprised at how much use you can make of the limited information the amulet provides. As well, you'll get a brief glimpse of the cave system from above at the start of the game, and from time to time as it goes on.

This is the program listing to enable you to become
THE DUKE OF DRAGONFEAR:

Simulations

Simulations

Simulations are ways of producing a counterfeit reality. In contrast to ADVENTURE, where the reality created via the computer is often magical and dream-like, the worlds accessed through computer simulations are generally more down to earth.

In a simulation, the computer manipulates variables in accordance with formulae you've specified, keeping tabs on the unfolding of the situation you've generated, and taking the place of the environment in terms of reacting to your input.

Simulations attempt to replicate life. However, because reality is notoriously hard to pin down and limit, we need to do some pretty drastic simplification before we can produce a workable simulation.

Despite this simplification -- as you'll soon see -- a well-written simulation can imitate life to an uncanny extent. Cause and effect are linked as accurately as you can devise formulae for them. The random number generator can take the place of such things as changes in the weather, in population numbers, in the behavior of molecules in a gas or the way a colored ink is dispersed through a clear liquid.

In this section of the book we have three simulations. One of them -- MISTRESS OF XENOPHOBIA -- is simple to the point of absurdity, but it is great fun to play, as you tinker with the fate of an entire planet. The other two -- RURAL PURSUITS (where you run a farm with extremely fickle workers) and CHAIRMAN OF THE BOARD (where you run a factory that could produce any one of a range of products including kazoes, pith helmets or sky hooks) -- are a little more serious, and the formulae employed in them produce results a little closer to 'real life'.

Despite the seriousness of the last two I mentioned, they are still great fun to play, as you'll see when you get them up and running.

If you want to know more about writing simulations the booklet Designing Classroom Simulations by Glenn Pate and Hugh Parker, Jr., will be of help. As well, Creative Computing magazine has printed two articles which are very valuable. These are "How to write a computer simulation" by the magazine's erstwhile editor, David Ahl, which appeared in the Jan/Feb (1978) issue of the magazine (and is the text of a talk David presented at the Conference on Computers in the Undergraduate Curricula in Pullman, Washington, in June 1974), and "Strategies for Successful Simulation" by Bruno B Wolff, Jr. which was in the August 1981 issue. It is worth checking your library for these back issues, as you'll learn a lot of value by reading them. Of particular interest in the Wolff article is a set of four equations which link cause and effect and can easily be adapted for a simulation you write.

MISTRESS OF XENOPHOBIA

We'll start our exploration of simulations with the silliest one of the lot, MISTRESS OF XENOPHOBIA, which is based on a program written by Alastair Gourley, a talented programmer who lives in Glasgow.

There's no need to explain MISTRESS, as the program gives you all the prompts you could need.

RURAL PURSUITS

If you've survived being MISTRESS OF XENOPHOBIA, you may be interested in something a little more earthy -- running a farm. In RURAL PURSUITS, based loosely on a program written by Stephen Glen, also of Glasgow, you have a very difficult task, as you battle with an extremely touchy work-crew to bring home the bacon (or at least the wheat and barley).

Again the program is largely self-prompting, and working with it will teach you the best strategy for gaining a maximum return from your farm (and surviving for the requisite 10 years to win the game). However, a few hints will not go astray. Although you can save money by paying your workers extremely badly, you'll find they'll desert you in droves in the following year, and the return you get from your land is dictated, to some degree, by the number of people you have working on the land.

Another factor to keep in mind is that the three crops which you can plant have quite different returns, so it is in your interest to work out which is the most profitable crop, and concentrate on that.

Do not be dismayed if you foul the process up the first few times you run the program. You'll have to develop some real skills to keep your farm solvent, and it may take you several bad years to get the hang of it.

CHAIRMAN OF THE BOARD

Finally in this section we have our major simulation, CHAIRMAN OF THE BOARD.

Again the program is largely self-prompting. The aim of the game is to keep your factory running until you manage to make \$10,000 (in total, combining the value of stock in hand plus your capital). You have to deal with recalcitrant unions (who won't always let you fire the people you wish to get rid of, and have a great appetite for pay rises which you cannot deny), with workers who will hardly ever meet the production targets you set, and raw material suppliers who enjoy putting their prices up as much as the unions enjoy slugging you for more pay.

You'll find, in contrast to the other two programs which are only very vague approximations to 'real life' that the life and health of your factory will become very important to you, and you'll certainly learn ways of manipulating resources for maximum return. Keep in mind that although you have great freedom in setting the retail price of your products, each rise in price will increase consumer resistance to purchasing those products.

Dice Games

Dice Games

Dice games -- for high stakes, low stakes or none -- have proved popular throughout history. Whether the dice were made from stone or wood, or carved from the bones of a beast killed for food, whether they had four important sides or six, dice have proved a diversion for countless men throughout time.

The dice, physical means of demonstrating the waywardness of chance, have also found employment in foretelling the future, and like all oracles, probably bear some responsibility for changing the tide of history.

At Troy the Greeks played with dice, as did Mark Antony at Alexandria. Italy and France led medieval Europe in its love for dice, and devotion to the six-sided cubes has continued up to the present day. In this section of the book, we'll be investigating ways of using the random number generator of your computer to take the place of physical dice. However, you'll discover that the dice are no less compelling because they exist only within the software of your computer rather than in a more gross physical form.

Playing against the computer, instead of against another human being, changes the 'feel' of dice games somewhat. Not having to pay up when you lose is one of the real advantages!

To start our dice games, here's a routine you might like to incorporate into some of your own dice programs:

```
2000 REM DICE THROW
2010 CLS:COLOR,1

In this program, the variable D represents the die thrown, and DN represents the dice number.

An enormous range of games is now played with dice and they sport an intriguing variety of titles. Here are some names of common dice programs:

- Going to Boston
- Craps
- Fifty
- Crag
- Baseball
- Basketball
- Poker Dice
- Liar Dice

The dice games we'll be playing in this book are SNAKES EYES, ONE-AND-TWENTY, SEVEN/ELEVEN, OVER/IN/UNDER, NO SWEAT and CHEMIN DE COMPUTER.

CHEMIN DE COMPUTER

CHEMIN DE COMPUTER is based, as I'm sure you've realised, on Chemin de Fer. In this game, you and your computer take it in turns to roll five dice, adding the pips up as you go. You are aiming to get a higher total than the computer.

However, this game is not just a simple 'add the pips' one. Any die which falls showing a five or a two must be thrown again, and your total is just the final digit of the answer (that is, a total of 27 is counted as 7, and a total of 13 is counted as 3).

There are three special totals - 7 (Natural), 8 (Petite) and 9 (Grande). The names are only bestowed on the roll when the relevant total is achieved on the first throw (i.e. the dice which came up with 5 or 2 have not been, and are not in this case, rethrown). You (and the computer) always stand on a 7, 8 or 9 thrown with the first toss of the dice.

As in many other programs in this book, there is a delay loop routine at the end of the listing which is called a number of times throughout a game to improve the speed with which the game advances, and to give you (in many cases) a chance to read on the screen what is going on before the program races on, clearing the screen, and leaving you quite unsure of exactly what has just happened. In this program, there are two loops, one which is longer than the other, and which also prints a couple of blank lines before returning to the main program.

SEVEN/ELEVEN

SEVEN/ELEVEN is another fine dice game, and one in which your goal changes in each game. Based on CRAPS, you have a 'target number' to reach in each round (known as your 'point' in Craps).

Craps is an American version of the old English dice game Hazard. In SEVEN/ELEVEN, the complex betting of craps has been removed, leaving just the fun of the game. Rather than worry about computing odds and placing 'pass' and 'don't pass' bets, you can concentrate on the serious business of praying for the right roll to come up.

In this game, you are playing against yourself. Your winning and losing rounds are tallied, so you know -- at every point in the game -- just how well (or otherwise) you are doing.

You throw two dice at a time. If you throw a 2, 3 or a 12 with your first roll, you lose that round. Getting a 7, or an 11, on the first roll is the best thing you can do, because you've won that round with that single roll (which is why the game is called SEVEN/ELEVEN).

Any other number rolled as your first roll of a round becomes your 'target number'. You have to try and roll this again, before you roll a 7 or an 11. If you manage to roll your target number again, you win that round. However, rolling a 7 or an 11 before you've rethrown your target total, causes you to lose that round.

```
10 REM SEVEN ELEVEN

```

NO SWEAT

The name of this game -- NO SWEAT -- comes from one of the the early English names for the game from which this is derived. Known as 'Sweatcloth', the game, when first played in England, used three dice within a wooden 'shoe'. The most common variation of this game is now seen in US gambling casinos where it is called 'Birdcage', because of the equipment which is used.

In Birdcage, three dice are held within a metal cage which can spin about a central axis. Once bets have been laid, the cage is rotated. This is supposed to ensure that the dice are spun properly, as they are not actually touched by a casino operator.

Betting in Birdcage, and in No Sweat, is fast and simple, and despite the fact that you might think the odds are in your favor as a player, you'll quickly learn how easy it is to lose your shirt.

You place a bet of a specified amount (see lines 50 and 60) up to the size of your stake (held by the variable M, for money - see lines 30 and 250) and then choose a number between one and six. The amount of your bet is subtracted from your stake, and then the three dice are rolled. For each one which lands showing your number, you'll have an amount equal to your bet returned to you.

As you can see, this means you have to throw one die with your number showing to break even, and two to actually make some money. The need to throw the same, chosen, number twice is what gives the casino such a good edge in this game.

Line 50 asks you how much you'd like to bet, and the variable A is assigned to your choice. This is compared with the money you actually have (in line 60) to see if you are trying to bet more than you have on hand.

The C loop, from lines 100 to 180 rolls the dice and compares each roll with your number, reporting to you after each roll. Your winnings (if there are any) are also added in this loop.

After each round of the game, your money (M) is compared with 250 (if you've got more than \$250 you've exceeded the house limits and are therefore excluded from future play) and with zero (those who have no money are not allowed to play further). If however, you do not have more than 250 nor less than zero, you're able to continue playing.

ONE-AND-TWENTY

Our dice games continue now with ONE-AND-TWENTY which, as you realised the moment you read the title in the introduction, is a dice version of the card game, Pontoon.

The game is simple, but demands a degree of cool thinking, as well as the ability to guess which numbers are going to come up next when the die is rolled. In ONE-AND-TWENTY, you are playing against the computer.

You are always given the first go. You roll the die as many times as you like, aiming to get a total as close as possible to, but not exceeding, 21. You can stop adding to the total whenever you like.

If you exceed 21 (that is, you 'bust') then the computer wins that round automatically. A game consists of five rounds, and the winner of the most rounds, naturally enough, wins the game.

The lines from 50 to 170 control your dice-rolling, and the computer only exits this cycle when you decide to stand. The whole of the computer's game playing logic is held within line 180 which determines whether it is worth risking a bust to try and exceed your total. If it decides to roll, the lines from 180 to 250 control this.

Once the computer decides it has had enough of that, it uses lines 260, 280 and 290 to determine who has won. If both your scores are the same, or both of you are over 21, then the round is counted as a dead heat (line 320 tells you this), and neither CS nor HS is incremented.

As in Chemin de Computer, where the aim was to get the best out of nine scoring games, in One-and-Twenty, the intention is to score wins in the majority of games out of five.

SNAKES EYES

SNAKES EYES demands some more cool thinking under pressure. You and your computer take it in turns to throw a pair of dice. You add the total of the pips, and in turn add this to your score.

You can roll the dice as many times as you like, but if you roll a seven, you automatically lose. Therefore, as you can see, the program demands you make decisions based on whether you should be careful and perhaps lose the round by not rolling a high enough score, or whether you should be greedy and go for the absolute maximum score and risk a seven.

The Q loop is covered 20 times, gradually slowing down as it is traversed (by the inner loop, in line 430), until finally -- with line 420 -- the results of the dice rolls are printed. The variable Z is set equal to the tally of the two rolls (in line 480) before the computer goes to line 700 for the delay and to print a line across the screen, and then returns to the start of the program to line 180, the one after the one which sent it to the 'roll the dice' routine. Here the computer checks that the total is not 7 (line 180) and if it is not, then adds the result of the latest roll to your tally.

If, however, you signal through INKEY\$ that you wish to quit, the action goes to the routine from line 220. After printing STAND BY, the computer goes to the delay loop, and line print routine, and then uses the same routine as the human did for rolling the dice, and -- on returning from the subroutine -- checking that the total was not 7, and if not, adding the new total to the score. The computer has a very simple means of deciding if it will roll again...if it has less than the human, it takes the risk.

You'll find that it is relatively easy to program games like this on your computer. Once you've worked out the 'mechanical routines' which do such things as roll the dice, and increment the score, for the human player, it is not very difficult to work out a routine to enable the computer to use the same mechanical routines. Most dice games do not demand much 'intelligence' and their strategy can often be reduced to a couple of IF/THEN statements. Read books on dice games -- such as the excellent DICE GAMES OLD AND NEW by William E Tredd (The Olesander Press, New York, 1981) -- to get ideas for games to turn into programs, and for simple ideas on how to play the game as well as possible. It is these ideas which you should find relatively easy to turn into simple 'intelligent algorithms' to enable your computer to play reasonably well against you.

And, if as in this case and in ONE-AND-TWENTY, you stipulate that the human must go first, the computer knows exactly what target it is aiming at, and therefore starts a round with a considerable advantage, which helps overcome the machine's inherent stupidity.

UNDER 'N' OVER

UNDER 'N' OVER is a computer adaptation of the dice game usually known as 'Under and Over Seven'. In this game, you bet on the likelihood of the total of pair of dice landing so that the total is:

- less than seven;
- exactly equal to seven; or
- greater than seven

Again, this is a game which -- at first sight -- seems to offer pretty good odds to the player. However, if you played the game forever, with a pair of perfect dice, you'd find your losses would outweigh your wins by nearly 17%.

Lines 70 to 120 ask you to place your bet, giving you the key for entering it (press A to bet under seven, B to bet on seven and C to bet on a total greater than seven). Lines 130 and 140 read the keyboard using INKEY\$, rejecting (line 140) any input which is not A, B or C.

Having received a valid choice, the odds are printed up by lines 150 to 180 and then line 200 asks you to enter the amount of your bet. Of course, you can't bet more than you have (not in this game, anyway) so line 220 checks your bet (A) against your money (M).

The next section rolls the dice, assigning random values between one and six to variables B and C, and adding them to produce total D in line 280. You are told of the total by line 300.

THE OUTCOME

This is determined by the routine from lines 310 to 350 where a loss is first assumed (line 310, with variable W, for 'win', assigned to the negative of

your bet). This is changed -- if needed -- into the correct amount for a win if one has, in fact, taken place. You can see you get paid four times your bet for correctly specifying the dice will land with a total of seven (line 320) and even money for either over or under seven (lines 330 and 340).

Lines 370 and 380 tell you about your win (or loss) and then line 420 checks that you still have some money in hand. If you have, you are offered a new round of the game. If not, you are dismissed with a certain severity.

Artificial Intelligence

Artificial Intelligence

Artificial intelligence is a goal which has not yet been achieved. Certainly, programs which enable computers to exhibit behavior which could conceivably be classed as intelligent have been written, but the 'intelligence' has been limited and effective only within a severely restricted domain. That is, a computer can appear to be brainy, but only if you limit the environment within which it has to demonstrate those brains.

In this section of the book, we have four programs which will give your computer the appearance of intelligence, and certainly provide impressive demonstrations of 'electronic brainpower' when the programs are shown to computer-naïve people.

Despite the claims made by some people (such as Carl Sagan, "In Defense of Robots", Broca's Brains) that human beings are, essentially, just well-made computers, we sense there is a wide gulf between our own perception of our selfhood, and the total non-awareness that computers can have (at least at present) of their own existence. And it seems to me that this self-perception lies at the heart of at least one aspect of intelligence.

Computers can function extremely 'intelligently' in restricted areas. Look at the five inch square, hand-held chess machines. Within the limited domain of chess game, a solid appearance of intelligence can be created.

A common stumbling block in the work of early researchers into the field of artificial intelligence was that writing a program which emulated some aspect of human reasoning (such as a very impressive Checkers program by Samuel's) did not necessarily lead researchers any closer to either producing behavior

which could be classed as intelligent, nor towards a theoretical understanding of the processes of human reasoning and deduction. "Progress in producing intelligent behavior is not necessarily progress towards producing thought" (Norman Whaland, When Is A Program Intelligent?, Creative Computing, February 1981, pp. 44 - 49).

There is another way of approaching the problem, which I call the "if it quacks like a duck, it's a duck" approach. In the book "The Turing Criterion - Machine Intelligent Programs for the 16K ZX81" (Charlton et al, Interface Publications London, 1982), which I edited, I answer the question "What is the Turing Criterion?" in the following words:

"In 1950, the English mathematician and logician A. M. Turing proposed what has become known as the 'Turing Criterion' for machine intelligence.

"He said that if you were dealing with something at the end of a wire that could be a machine, or could be human, and you could not tell -- from the responses coming to you over the wire -- whether that with which you were dealing was human or machine, the 'thing' at the other end was, by definition, intelligent.

On this basis, it would be possible to class many, many computer programs as intelligent. Certainly those within this section of the book could almost pass the test, especially if you were prepared to accept the possibility that some pretty stupid humans were dealing with you.

Time now to explore the world's of Artificial Intelligence with the following programs:

- * Electronic Brain (in which the computer tries to crack a 'mastermind-like' code you've worked out
- * Amanuensis (in which the computer accepts the task of writing poetry)

ELECTRONIC BRAIN

ELECTRONIC BRAIN is an attempt to write a program to crack a 'Mastermind' type code in an apparently intelligent manner. You think of a numerical code, and the computer tries to guess it. You tell the computer how well it is doing by awarding - after each guess it makes - a 'black' for any digit correctly guessed in the right position within the code, and a 'white' for any digit which appears within your code, but not in the position the computer indicated.

The problem is not totally straightforward, as the computer does not know, for certain, which digit produced which result. I wrote two versions of this program, one to solve three-digit codes, and a modification of that program to solve four-digit ones. It works in a simple manner (although implementing the relatively simple idea behind the program was not particularly easy). Everytime a digit appears in a code which is awarded a black, every digit within that code is weighted so that it appears more often in future guesses. The more blacks in that particular code, the higher the weighting each code gets. A much smaller weighting is awarded if the code gets one or more whites. Any code getting neither a black nor a white leads to all the digits within that guess being totally removed from future consideration.

As I said, the three-digit version is the basic upon which the four-digit program was written. Enter the three-digit one first, and then save it in that form, before making the needed conversion to make it work as a four-digit program. Whereas the three-digit version works reasonably well, and reasonably quickly, the four-digit program grinds almost to a halt towards the end, as it tries to generate codes

which (a) reflect the weighting that previous answers have produced, and (b) are not codes which have been previously suggested in that particular run.

Here's the program solving a three-digit code:

GUESS NUMBER 1

MY GUESS IS 1 2 3

HOW MANY BLACKS? 1

AND HOW MANY WHITES? 0

GUESS NUMBER 2

MY GUESS IS 4 5 6

HOW MANY BLACKS? 1

AND HOW MANY WHITES? 0

GUESS NUMBER 3

MY GUESS IS 7 8 9

HOW MANY BLACKS? 1

And this is the listing that produced it:

```

10 REM ELECTRONIC BRAIN-3 DIGITS
20 GOSUB 500:REM INITIALISE

60 GOSUB 280
70 CLS
80 GUESS=GUESS+1
90 PRINT:PRINT

```

AMANUENSIS

Next we'll have our poetry writing program. This demands no interaction from you, except for that of admiring the wonderful (!) output of the program. Here's a sample of the kind of verse it produces:

THE CONVOY CLAIMED SLAVISHLY
IN THE COURT...
PRAYING FOR AN ASTRAL INFLUENCE,
TO DEMUR THE FAUN...
EXHAUSTING, THEN GNAWING
...IMPOUNDING, BREAKING.

THE POSTULANT BESEECHED NEGLECTFULLY
IN THE ENEMY'S CAMP...
WANTING FOR A DOGMATIST,
TO RECAT THE DJINN...
DISPENSING WITH, THEN BRODING
...ENCLOSING, WOUNDING.

THE ASPIRANT CRAVED SUCCESSFULLY
IN THE RACECOURSE...
PRAYING FOR HOBSON'S CHOICE,
TO QUENCH THE GHOST...
EMPTYING, THEN BLIGHTING
...HANDCUFFING, ROTTING.

THE ASPIRANT ENTREATED HALTINGLY
IN THE HIPPODROME...
PRAYING FOR A BLIND BARGAIN,
TO RECAT THE NAIAD...
WASTING, THEN BREAKING
...RESTRAINING, UNDERMINING.

THE POSTULANT ENTREATED ENDLESSLY
IN THE PLAYGROUND...
WAITING FOR HOBSON'S CHOICE,
TO RELINQUISH THE SATUR...
DISPENSING WITH, THEN DAMAGING
...COERCING, BREAKING.

THE BEGGAR CLAIMED HALTINGLY
IN THE THEATRE OF WAR...
ASKING FOR FORTUNE'S WHEEL,
TO BACK THE NAIAD...
DISPENSING WITH, THEN BREAKING
...MUZZLING, WOUNDING.

This is the listing of AMANUENSIS. Once you've run it for a while, you may well wish to change the words in the DATA statements, to vary the kind of poetry it produces.

```

Just for Fun

Just for Fun

There is a range of games in this section of your book, all designed just for fun. From INNER SPRING to ROBOT NINEFIELD, a splendid time is guaranteed for all.

We'll start the 'just for fun' with a program which allows you to use your computer as a two-octave piano. It will be very clear how to play it when you get it up on the screen. Note that the X's in lines 50, 70 and 90 should be replaced with inverse spaces [with the exception of the third X in line 90, which stays as an X].

```

```

INNER SPRING

We'll continue this section of the book with one of the simplest games of the lot, INNER SPRING. As the program explains, the computer produces two numbers between one and 13, and asks you to bet on the probability of the next number it thinks of lying between the first two. It's simple to play, and a lot of fun.

Here's what one round looks like in action:

MY FIRST NUMBER IS 2
MY SECOND IS 4

YOU HAVE \$ 2

HOW MUCH DO YOU BET
MY NEXT NUMBER LIES
BETWEEN 2 AND 4 7 1

MY NUMBER WAS 3
WELL DONE, YOU WIN \$ 2

And here's the listing of INNER SPRING:

```

10 REM INNER SPRING
20 GOSUB 330
30 GOSUB 80
40 IF D<1 THEN GOTO 420
45 IF D>1000 THEN 330

ROBOT MINEFIELD

Time now to face the terrors, the dangers, and the horrors of the ROBOT MINEFIELD. There you are, peacefully tripping along one day in the sun, when suddenly you find yourself trapped in a walled area, with a number of manic robots, all bent on your destruction.

The robots are shown on the display as dollar signs, the M is you, and the asterisks (*) are the mines which are deadly to both you and robots. Robots, pretty clumsily programmed, can detect you, but they cannot detect mines. Therefore, your salvation lies in getting a mine or two in between you and the robots, so that when they come towards you they'll smash into mines and be wiped out.

The robots have one trick up their sleeves. They can merge into one another, so you may think only one robot is approaching you, when at the last minute it splits into two or more, one going each way around a mine. This is not a game for those who seek the quiet life.

You can move north, south, east or west (with north at the top of the screen), and you enter the move you want to make by entering the initial of the desired direction (so you enter "N" to go north, "S" to go south and so on).

```

Fun with your Printer CELESTIA

The first of the two programs in this section is CELESTIA, which you can run either on your TV screen, or on the screen and to the printer at the same time. It produces an infinite series of evolving patterns.

The patterns develop according to the rules of the famous computer game of LIFE, developed by John Conway while at Gonville and Caius College at Cambridge in the UK. Martin Gardiner spread the game throughout the world when he wrote about it in Scientific American in October, 1970.

In LIFE, cells are born, grow and die according to rules which Conway invented. Each cell on a grid (the colony of cells is imagined to be evolving on a grid) is surrounded by eight others, and the state of those eight other cells dictates what happens to the cell in question in the following generation.

The rules which govern the evolution of the cells are as follows:

- * If a cell has two or three surrounding it, it survives to the next generation

- * If there are three, and just three, full cells next to an empty one, a cell will be 'born' in that empty space in the next generation

- *Any cell with four of its neighbouring cells occupied dies in the next generation

Don't worry, you don't have to know the rules, as the computer interprets them quite happily by

itself. The rules produce patterns which are far more attractive (and far less predictable) than you could possibly imagine by reading the rules. There is just one extra twist in this program, which makes it even more effective. CELESTIA actually prints out four colonies each time a colony evolves. The original colony is in one quadrant of the screen, and the other three quarters of the screen contains reflections of the original one.

CELESTIA is incredibly effective, as you can see:

This is the listing to give CELESTIA designs on your microcomputer:

```

10 REM CELESTIA
20 GOSUB 450:REM INITIALISE

BILLBOARD

BILLBOARD, as you can see from the following sample run, takes a message of any length (up to the maximum string length permitted by your system) and turns it into a printed message down the side of your printer paper. The printed letters can then be used to decorate your walls, cut up to form posters, or used however your imagination dictates.

You don't need any further instructions to get great results like these:

[illegible]

Space Games

Space Games

Good old space, the final frontier. No collection of computer games would be complete without a few space games.

MOONLANDER

The scenario of this program is pretty familiar. You are landing on the moon, with limited fuel, and for some reason your onboard computer is incapable of doing anything except reporting the state of the flight to you. The information you get is, of necessity, limited but adequate.

You are told, at all times, your height above the moon's surface, how much fuel you have left, and the speed with which you are descending. You have to enter the correct amount of thrust to ensure you land gently on the surface. The fuel you have is limited, so you must ration it to ensure you have enough left in the last few seconds of flight to cushion your impact. A 'high-score' feature (lines 370 and 380) ensures you and your friends return to this program time and time again in an effort to get a better 'galactic rating' and to creating a less deep crater.

```

HYPERWAR

HYPERWAR is a major space simulation, which puts you in charge of patrolling a cube-shaped sector of space, which is ten parsecs along each side. The enemy is the race known as the Dosznti. There is only one Dosznti ship in this sector, and it is moving slowly through the cube as you play. Although you cannot destroy the ship, you can kill a number of individual Dosznti. In fact, the aim of the game is to get your 'alien kill total' to the highest point possible before your energy banks are exhausted. Although there are many, many more Dosznti in this sector than there are humans, the aliens are notoriously bad shots, so your chance of wiping out a lot before your mission is terminated is rather high.

You can only fire at the Dosznti when you are within three units of their position. Attempting to fire when they are out of range leads only to the crew response 'THE DOSZNTI SHIP IS NOT WITHIN RANGE, SIR'.

You have a limited amount of energy, and each successful hit by an alien craft diminishes your energy supply.

I will not explain the game in any more detail, because to do so would diminish the enjoyment you'll get from playing it. The 'behaviour of space' does not change from game to game, so you should find you begin to learn the tricks of space warfare after the first game, leading to higher and higher scores as you continue to play it. The game tends to explain the rules to you as you play, and the screen display has been organised to make it as clear as possible what is going on.

Brain Games

Brain Games

I guess 90% of all games could, without stretching the definition too much, be called 'brain games'. After all, they demand a certain amount of brain-power and application from you to play.

However, the programs in this section under the heading of BRAIN GAMES are here because they demand a little more intellectual effort than several of the other games in the book.

Here you'll test your ability as you solve magic stars in IDAHO STARS and save your precious neck by deducing a word the computer has chosen in EXECUTIONER.

As well, you'll try to unlock a twisted cube in CUBIC, will settle down to a game or two of HUMBLE MARBLE (generally known as a "Solitaire" and named, in this case, because the game in 'real life' uses marbles on a board) and will have to work under the pressure of a relentless clock to locate some atoms within a CYCLOTRON.

If your brain still has any power left after all that, you can attempt a task which may appear impossible in FLIPPER.

IDAHO STARS

IDAHO STARS are stars with a special property -- numbers placed on the cross-over points of the lines forming them will, when added together, produce the same total, no matter which line of numbers is chosen.

Here, for example, is one such star:

As you can see, each line on the star sums to the same total. In this program, the computer generates an IDAHO STAR, leaving two or three of the numbers as zeroes for you to work out as quickly as you can.

```

10 REM IDAHO STARS

EXECUTIONER

As you can tell, this game is a computer variation of the old pencil-and-paper game HANGMAN. In this game, the computer chooses a word from its store (held in the DATA statements from 500 to 740) and then challenges you to guess it.

The number of guesses you'll get is related to the length of the word (see lines 120 and 170).

```

CUBIC

This is a two-dimensional version of the colored cube puzzle which swept the world from Hungary.

The 'cube' starts off looking like this:

1	1	2	2
1	1	2	2
3	3	4	4
3	3	4	4

After some manipulation by the computer, it will look something like this:

1	2	1	2
3	3	3	2
3	1	4	1
4	2	4	4

Your job is to get it back into its original state in as few moves as possible. The numbers on the cube rotate in groups of four, spinning in a clockwise direction. This means 1 2 3 4 when rotated will look

like this 3 1
4 2

You enter a number in order to rotate the elements of the cube. The key to move is as follows:

2	9	4
6	7	8
10	11	12

```
30 DIM A(4),B(16)

MUMBLE MARBLE

Our next brain game is a computer version of the game you probably know as 'Solitaire' in which you have to move marbles around a board. At the start of the game only the center hole is empty. You can jump over marbles into empty holes, and you remove the marble so jumped over. The idea of the game is to end up with just one marble in the center hole.

Many stories have been told about the origin of this game. The most interesting of these tales is the one that says the idea of the game was worked out by a prisoner in solitary confinement in the Bastille, who devised it as a way to relieve the monotony of his imprisonment. Whether that story is true or not, there is no doubt that the game can become quite addictive, as you try to devise a foolproof way to solve it.

Here's what the MUMBLE MARBLE display looks like at the start of the game:

1	2	3	4	5	6	7	
		0	0	0			1
		0	0	0			2
	0	0	0	0	0	0	3
	0	0	0	*	0	0	4
	0	0	0	0	0	0	5
		0	0	0			6
		0	0	0			7

A few moves later it could look like this:

1	2	3	4	5	6	7	
		0	0	0			1
		0	*	0			2
	0	*	0	0	0	0	3
	0	0	*	0	0	0	4
	0	0	0	0	0	0	5
		*	0	0			6
		*	0	0			7

```

CYCLOTRON

In CYCLOTRON, you fire atoms into the machine from the top, by specifying a number, and you have to try and locate particles of antimatter hidden within the machine from the behavior of the atom.

If the atom hits a particle of antimatter it will either be absorbed, or deflected to the right or left. An atom may be effected by more than one particle of antimatter which makes the resolution of the problem even more difficult.

There are always three particles of antimatter in the machine, although they could well all be in the same number cyclotron. You have an extremely limited number of goes in order to locate the antimatter. At each go, you can either enter the number where you want to enter an atom, or be reckless and enter 8, which gives you the chance to guess the location of the antimatter particles.

FLIPPER

This intriguing game can provide you with a considerable degree of mental stretching. When you run the game, you'll see a mix of X's and *'s on a three by three grid. You have to end up with an X in the middle, and eight *'s surrounding it.

You enter the number of the place you want to hit with your flipper. Flipping a corner piece causes those adjoining it to change into their opposites (that is an X becomes an *, and an * becomes an X). Hitting the middle piece on a side with your flipper causes the two on either side of it to change, and hitting the middle piece changes the middle pieces on each of the sides.

The piece you hit always changes in each case.

```

Creating your own Games

Creating Games

You may well find, after you've been programming for some time, that although you've got many of the skills you need to write games of your own, you're a little short on ideas. If that's the case, you should find this section of the book of interest to you. I'm going to outline a number of games which seem to me to be ideal for conversion to computer games.

GAMES TO ADAPT

SHUFFLEBOARD: Players slide flat, circular pieces along a board towards a triangular 'target' which contains painted circles with numbers on them. A piece ending up entirely within the numbered circle gives the player the score of that number. There are many possible variations of this, including darts-like target games. Once you get a shuffleboard program running, you may well find that only cosmetic changes are needed to convert it into a ten-pin bowling game.

HORSESHOE: Starting with a board like this, with one player's pieces at the positions marked A, and one at those marked B, the players take it in turns to move along a line to a vacant spot:

The game ends when a player discovers he or she (or it) cannot move. Despite its simplicity, this is an interesting game, as you'll discover when you play it.

MU-TORERE: This game, which originated among the Maoris in New Zealand, is played on a board shaped like an eight-pointed star, with each point of the star joined to a circle in the middle. This circle

is called the putahi. The players start with four pieces each, which are placed on the outside points, with all of one player's pieces occupying points next to each other. The aim of the game, as in the last two we've discussed, is to make it impossible for a player to move. You can move from one point to an adjacent empty point, or from the putahi to any vacant point. The third possible move is from a point to the putahi, but this move can only be made if at least one of the points immediately adjacent to the one from which you intend to move is occupied by an opponent's piece.

BINGO: This game is usually played with cards marked with numbers, which are crossed off as numbers are drawn at random from a pool, the winner being the player who first crosses off five in a row on their card, in any direction. It can be greatly simplified for computer use, with the computer generating two 'cards' at random, using numbers from zero to 99, and printing them on a five by five grid. The computer can then choose numbers at random from zero to 99, and do the crossings off, and look for possible wins. The program can be made more interesting to look at by, instead of just generating a random number, including two 'dials' with spinning arrows. The first dial, the 'tens' is marked from zero to nine, and this is spun first. The second dial is marked the same as the first one, except that it represents the 'ones'.

DICE GAMES: As I said in the notes regarding the dice games in the dice section of this book, you should find dice games relatively easy to program on your computer, especially if the computer is not expected to exhibit too much intelligence when playing. There are a number of dice games which you may wish to try and adapt for computer play, including:

DROP DEAD: You need five dice for this. The dice are thrown by the first player, and any which show two or five are removed. The total of the rest is written down, and the dice which fell with a two or

a five are thrown again. After this throw, the dice landing two and five are removed, and the total of the remaining dice is added to the total from the first throw. This process continues until there are no dice left, at which point that particular player's move ends. It is then player two's go, and the same procedure is followed. The winner is the player with the biggest total after both have had their throws. You can make the game the best of, say, three rounds, or limit the total number of throws any player can have per go, regardless of how many dice he or she has left.

MARTINETTI: You need three dice for this, and a score sheet marked with a row of boxes marked from one to 12, and two tokens, one each for you and the computer. You are aiming to traverse the numbers in order, before your opponent manages to do so. Each player takes it in turn to throw the dice. If the throw contains a one, the player's token can be placed in the one square. If the first throw also contained a two, the token could be moved into the two. After box one, players can either take the pip shown on an individual die for a move, or can add together the pips showing to get a desired number. A variation of this game (often called EVEREST) is to 'climb down' through the numbers, after one through to 12 has been achieved. The winner of EVEREST is the first player getting back to base camp on one.

INDIAN DICE: This game is similar to POKER DICE and is played with five dice. The aim is simply to get the best possible 'poker hands'. There is no provision for getting additional 'cards' in one deal. You throw the five dice at once, and that is your hand. The ranking of the hands is as follows (with six highest and ones wild):

- five of a kind
- four of a kind
- full house (three of a kind plus a pair)
- two pairs
- one pair
- highest die

BIDOU: This game is also similar to POKER DICE, however, you aim to get rid of all your chips, rather than win them. The winner of the game is paradoxically, the person who has lost the most rounds. You need three dice for this game, and a supply of chips which are distributed equally between the two players. A bet is made, and matched, before the players take it in turns to throw the three dice. The throws are ranked as follows, with 'winning throws' coming first:

2 1 1; 2 2 1; 4 2 1; 6 6 6; 5 5 5; 4 4 4;
 3 3 3; 2 2 2; 1 1 1; 3 3 6; 3 3 5; 3 3 4;
 3 3 2; 3 3 1; 1 1 6; 1 1 5; 1 1 4; 1 1 3;
 3 2 1; 4 3 2; 5 4 3; 6 5 4

If the combination thrown is not in the list, the pips are added, with the highest total winning.

BARBOOTH: Also known as BARBUDI, this game is played with two dice, and features winning and losing throws. It is suggested you start with a bank of 30 chips, and give both players a starting stake of 15 chips each, charging two chips per player per round. The players take it in turns to throw the dice. Winning throws are 3 3; 5 5; 6 5; and 6 6. Losing throws are 1 1; 2 2; 2 1 and 4 4. If the players both get winning throws, the one closest to the start of the list wins (that is, 3 3 is better than 5 5). If both throw the same winning throw, the bank gets the money. If one player throws a combination which is not a winning one nor a losing one, and the other throws a losing throw, the loser's chips go into the bank, and the other player retains his or her chips.

If one player throws a winning throw, and the other a non-ranking combination, the winner gets his own chips back, as well as those bet by the loser. If, however, one player throws a winning combination,

and the other a losing combination, the bank contributes the same number of chips as have been bet in total. The game continues until either player, or the bank, runs out of chips. The player holding the maximum number of chips at this point wins. Note that this way of distributing the wins and losses is not the same as BARBOOTH when played as a 'professional' gambling game, but is a pay-off scheme which is relatively easy to computerise, and makes for an interesting game.

FIVE THOUSAND: There are no prizes for guessing that the first player to score over 5000 points in this game is the winner. Played with as many players as you like, all you'll need in the way of game equipment is five six-sided dice. Each player takes it in turn to throw the five dice, and scoring is carried out in the following way:

- a 5 is worth 100
- a 2 is worth 50
- three 5's thrown in one go are worth 1000
- three 2's thrown in a go score 500
- three of a kind (apart from 2's and 5's, are worth 100 times their value (that is three 1's are worth 100 points, and three 6's are worth 600
- if the sequence 1, 2, 3, 4 and 5 is thrown in a single go, this scores 1500
- 2, 3, 4, 5 and 6 in one throw are worth 2000 points

Note that 4's and 6's do not score in this game, except as part of a sequence. Once you've thrown, you can -- if you like -- throw the non-scoring dice again. However, if the next throw gains no score, the turn ends, and the overall score for the throw is zero. So long as a scoring throw has been made, any dice 'left over' can be thrown.

The game rewards the slow and careful player with a reasonable score, but gives him or her no chance against a player who decides to take a chance and try to get a massive score in a single throw.

CARD GAMES: Once you've worked out a routine to get the computer hold, shuffle and deal the cards (and such a routine is in my version of Concentration in this book) you have the raw bones of a host of games. Any book of card games will give you more ideas than you can possibly cope with. Here are a few to start you off:

TRENTE AND QUARANTE: This game, which originated in 17th century Europe, is also known as ROUGE ET NOIR. Six decks of cards are used in the casino version but it works well with a single deck. The cards are dealt into two rows, with the total of each row being examined after each row has had an additional card. Court cards (jack, queen, king) count as ten with all other cards (including the ace) counting as their face value. The moment the total of a row equals or exceeds 31, no more cards are added to that row. However, the dealer keeps adding to the other row until it, too, equals or exceeds 31. The first row is called 'black', regardless of the suit of the cards involved, and the second row is 'red'.

You can bet that, at the end, the red row or the black row total will be closer to 31. You can also bet that the colour of the first card to be dealt will match the colour name of the winning row. All bets are made against the bank, and winners receive their bet back, plus that amount again (odds of one to one). If both rows equal 31, the bank takes half the stake and returns the rest to the player.

CARD CRAPS: This game was devised to get around laws passed by some US States which outlawed craps played with dice. You use a special deck of 48 cards, made up from the aces, 2's, 3's, 4's, 5's and 6's, from two decks of cards. The game follows the standard rules of craps (which are similar to those used in the game SEVEN/ELEVEN in this book).

In its simplified form, without the somewhat complex betting combinations, you play as follows:

- a total of 2, 3 or 12 is 'craps' and the dealer loses, passing the cards to the next player to deal
- a total of 7 or 11 is a 'natural' and the dealer wins
- any other number (4, 5, 6, 8, 9 or 10) is the player's 'point' and he or she must continue dealing in pairs until the point is dealt again, at which point the dealer wins. However if a 7 is dealt before the point is obtained, the dealer loses

THREE CARD BRAG: This game was the forerunner of poker, and as its name suggests, it is played with hands of three, rather than five, cards. Here are the winning combinations, ranked from highest to lowest:

- 'pyle', three of a kind
- 'on a bike', three in sequence from the same suit
- 'run', three cards in sequence
- 'flush', three cards from the same suit
- 'pair', two of a kind
- 'high card'

A normal deck is used, and aces rank high, except for 'on a bike' and 'run', when 3, 2, ace beats ace, king, queen. You can vary the game by making it SEVEN CARD BRAG, in which the players split their seven cards into two three-card hands of their choice, or NINE CARD BRAG, when three cards are created.

ACE-DEUCE-JACK: This is a simple game, heavily loaded in the dealer's favor, in which players bet on the likelihood that the next card which appears will be an ace, a two (a 'deuce') or a jack.

PUT AND TAKE: This gambling game uses an eight-sided top, which is spun. The game begins with all players have 10 chips, with 30 in the pot. The players take it in turn to spin the top, and -- obeying the instructions which come up on the top -- put chips into the pot, or take them out. A player is out when he or she runs out of chips, and the game ends when the pot is empty. The instructions written on the sides of the top are:

- PUT ONE
- TAKE ONE
- PUT THREE
- TAKE THREE
- PUT FOUR
- TAKE FOUR
- PUT ALL
- TAKE ALL

BOULE: This is a simplified form of roulette which appeared in the 18th century. It is often found in European casinos. The wheel is divided into 18 segments, numbered from one to nine...twice. You can bet on the winning number, whether it will be a red or a black number, even or odd, high or low. Except for the fives on the wheel, which are usually yellow, the reds and blacks alternate, so that there is, for example, a red six and a black six, a red nine and a black nine, and so on. A 'high' number is above five, while 'low' numbers are below it. If you bet successfully on a single number, you'll be paid at seven to one, with a one to one return on the 'characteristic' of a number (such as it being 'high' or 'odd').

BOOKS TO READ

As you've probably gathered by reading through this book, I make a point of reading any book on games I can get my hand on. It doesn't matter whether the book is about computer games or the old-fashioned 'play against another human' type. So long as it is a book of games, I want to see it.

Games books are superb as idea-starters. Read about a game and you've got the seed of a program. And it doesn't matter if the program doesn't end up playing precisely the game you read about. Many great computer games started their lives as an attempt to computerise a more traditional game, and somehow got side-tracked.

I hope some of the following list of books prove as valuable to you as they have to me.

***DISCOVERING OLD BOARD GAMES** - R C Bell (Shire Publications, Aylesbury, UK, 1980)

***DISCOVERING DICE AND DOMINOS** - R C Bell (Shire Publications, Aylesbury, UK, 1980)

***DICE GAMES NEW AND OLD** - William E. Tread (The Oleander Press, London and New York, 1981)

***GAME PLAYING WITH BASIC** - Donald D. Spencer (Hayden Book Co., Inc., Rochelle Park, New Jersey, 1977)

***GAMES ANCIENT AND ORIENTAL AND HOW TO PLAY THEM** - Edward Falkner (Dover Publications, Inc., New York, 1961 - a reprint of an original work published by Longmans, Green and Co. in 1892)

***BASIC COMPUTER GAMES** - Ed. David H. Ahl (Creative Computing Press, Morristown, New Jersey, 1978)

***MORE BASIC COMPUTER GAMES** - Ed. David H. Ahl (Creative Computing Press, Morristown, New Jersey, 1979)

*28 BASIC PROGRAMS FOR YOUR MICRO - Derrick Dainoff
(Newnes Technical Books, Butterworths & Co., London
and Boston, 1982)

*TABLE GAMES OF GEORGIAN AND VICTORIAN DAYS - F R B
Whitehouse (Priory Press, Royston, Herts., UK, 1971)

*PET FUN AND GAMES - Ron Jeffries and Glen Fisher
(Osborne/McGraw-Hill, Berkeley, California, 1981)

*COMPUTER GAMES FOR BUSINESSES, SCHOOLS AND HOMES -
J Victor Nahigian and William S Hodges (Winthrop
Publishers, Inc., Cambridge, Massachusetts, 1979)

*GAMES YOU MAKE AND PLAY - Pia Heiso, Neil Lorimer
and Nick Williams (Macdonald and Jane's, London,
1975)

*WHAT TO DO AFTER YOU HIT RETURN - People's
Computer Company (Hayden Book Co., Inc., Rochelle
Park, New Jersey, 1980)

*EVERYMAN'S INDOOR GAMES - Gylas Brandreth (Dent
Everyman's Library, London, Melbourne and Toronto
1982)

*A PLAYER'S GUIDE TO TABLE GAMES - John Jackson
(Stackpole Books, Harrisburg, Pennsylvania, 1975)

*GAMES FOR TWO - John Wesley (Proteus, London and
New York, 1981)

*THE ADDISON-WESLEY BOOK OF APPLE COMPUTER SOFTWARE
1982 - Jeffrey Stanton and John Dickey, editors (The
Book Company, Lawndale, California, 1982)

*DICING WITH DRAGONS - Ian Livingstone (Routledge
& Kegan Paul, London, Melbourne and Hanley, 1982)

*FANTASY ROLE PLAYING GAMES - J Eric Holmes (Hippo
crane Books Inc., New York, 1981)

Here's a host of great programs, just waiting to be
fed into your Dick Smith VZ200 Personal
Colour Computer. No matter what kind of games you're
interested in, you'll find them here, to entertain
you in the weeks and months ahead. Now you can take
full advantage of the colour, sound and memory
available on the VZ200 to build yourself a library
of worthwhile and challenging games programs.

Tim Hartnell went to London from Melbourne in 1977
to work on the Australasian Express newspaper. While
in London, he wrote his first computer book, which
proved immediately successful. He has now written
more than 80 books on microcomputers, and brings the
experience gained from the books together in
this ultimate games book for your VZ200.

Tim was joined in the writing of this book by Glen
Pringle, a schoolboy from Lilydale, Victoria who
completed his major contributions to the work a week
before his fourteenth birthday. Glen intends to
make his career in computing, probably as a
programmer. As well as being interested in
computers, Glen reads a lot (mostly war books) and
is interested in international cricket.

You'll find much to entertain you in this volume,
including board games such as GOMOKU and CHECKERS.
As well, there are two adventure programs:
STRONGHOLD OF THE DWARVEN LORDS and
THE DUKE OF DRAGONFEAR. You can take part in
simulation programs like MISTRESS OF XENOPHOBIA or
run a company in CHAIRMAN OF THE BOARD. There is a
generous selection of dice games, such as ONE AND
TWENTY and CHEMIN DE COMPUTER.

If you're looking for raw entertainment, jump right
into ROBOT WINEFIELD and INNER SPRING. Out in space,
your VZ200 is waiting to entertain you with
NOONLANDER and HYPERWAR.

This is a just a sample of the action waiting for
you in this great book by Glen and Tim. Come
on in, the games are fine!
